

Role and Permission in Spring Security

Roles and Permissions in Spring Security?

In Spring Security, both **roles** and **permissions** are used to **control access** to resources.

A role is a named group of permissions that are assigned to a **user**. Users can be assigned one or more roles, and each role can be associated with one or more **permissions**. *Roles are typically used to manage access to entire sections of an application or to specific functionality.*

A permission is a specific action or operation that a user is allowed to perform. A permission might be "create", "read", "update", or "delete".

Roles and **Permissions** can be used together to implement a fine-grained access control system.
